Scottish Burden of Disease (SBOD) study

Measuring COVID-19 DALYs for the first calendar year, 2020

Grant WyperPublic Health Intelligence Adviser

Background and aim

- Disability-adjusted life years (DALYs) estimated by the Scottish Burden of Disease study for over 100 causes of disease and injury
- Integration of COVID-19, to allow for comprehensive, and comparable scaled assessments of direct and indirect pandemic harms
- Study aims
 - To estimate DALYs due to COVID-19, as a cause of disease, during the first calendar year
 - To frame COVID-19 relative to pre-pandemic causes of disease/injury
 - To assess socioeconomic inequalities in COVID-19 DALYs

Methodology

- Consistency with core Scottish Burden of Disease study (132 causes)
 - Outcome based DALYs (not pathogen)
 - Acute infection
 - Post-acute consequences (fatigue, emotional lability)
 - Use of routine morbidity and mortality data consistent with other causes
 - Stronger infection data than previously
 - Provisional cause of death data used with sensitivity (COVID-19 as main cause vs. COVID-19 as any cause)
- Methodology developed in collaboration with European Burden of Disease Network
 - Morbidity Wyper et al. 2020
 - Mortality (GBD aspirational life table) <u>Devleesschauwer et al. 2020</u>

Data inputs

Morbidity

- Severe and critical infections estimated from daily data on hospitalisations (with/without intensive care)
- Transmission model used to estimate the number of daily community infections, and total number of people infected
- Daily data allowed us to avoid assumptions over duration, as YLD was calculated on a daily basis – although crude durations: all cases (~8 days), hospitalised cases (~15 days)

Mortality

- Provisional cause of death data, based on date of death few weeks lag
- Data is highly credible, and unlikely to change when causes of death are finalised, as main changes occur for external (suicide, drug-related etc.) causes of death
- Consistent with how mortality is estimated in core SBOD

Making our methodology accessible for users

• Plain English communication via infographics and social media, supported by links to scientific papers for rigor and detail of methods

A 50-year old man suffered severe COVID-19 infection and was hospitalised. He took six weeks to recover, but suffered no further issues. This amounted to 0.02 lost years of healthy life.

Years Lived with Disability YLD = 0.02

A 45-year old woman suffered symptoms of COVID-19 infection and self-isolated at home. She took two weeks to recover and suffered a further six weeks of fatigue. This amounted to 0.03 lost years of healthy life.

Years Lived with Disability YLD = 0.03

A 60-year old woman died from COVID-19. Having lived to this age her aspirational life expectancy was 90.3 years, so there were 30.30 lost years due to premature mortality.

Years of Life Lost YLL = 30.30

Disability-adjusted Life Years (DALYS) = YLD + YLL

This hypothetical example resulted in 30.35 DALYs, representing the combined direct impact on ill-health and premature mortality.

#ScottishBurdenOfDisease

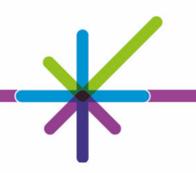

Findings – COVID-19 burden assessment

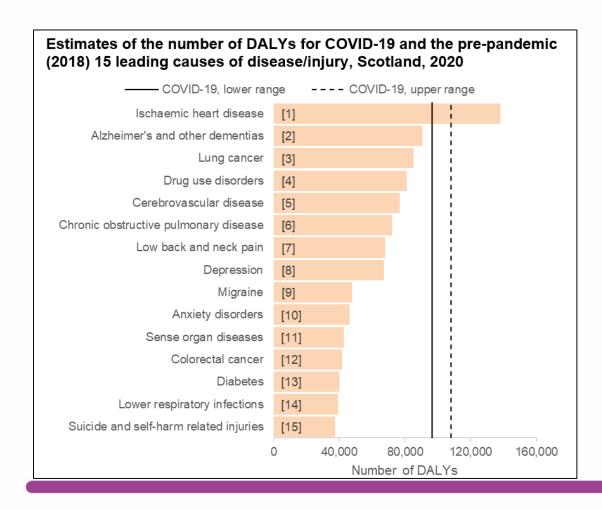

- 1,767 to 1,981 DALYs per 100k in Scotland, 2020 (N = 96,519 108,243)
- 15.3 to 15.5 YLL per death
- Post-acute consequences (<u>uncertain assumptions</u>) were the largest contributor to YLD, followed by community-based infections
- YLL contributed 98% of all DALYs

YLL, 98%

Findings – overall impact cf. pre-pandemic causes

- Upper and lower limits indicate COVID-19 likely to have been second leading cause in 2020
- Consistent across all sensitivity analyses
 - Community infection undercount
 - Transition/duration of post-acute consequences
 - GBD and SBOD estimates of other causes
- Changes in competing causes of death during 2020, unlikely to majorly impact this framing:
 - Respiratory (▼)

Conclusions

- Devastating impact a single case in March 2020, to second leading cause of disease/injury in 2020
- Expect that a high proportion of these DALYs are attributable to prior risk factors
- Need for a healthier society, as a means of achieving DALY reduction for COVID-19 and other future epidemics/disasters
- SBOD will continue to monitor COVID-19, and all other health conditions to estimate the largest contributors of disease, injuries and risk on population health.

Transferable learning

- Estimation for 2021 should indicate indications of the positive impact of DALYs averted due to vaccine rollout, and other continued mitigation efforts
- YLL is a close proxy for DALYs, so scrutiny over comparability of approaches to mortality assessment is of the greatest importance (for outcome-based DALYs, with COVID-19 as a cause)
- DALYs offer the opportunity to capture and monitor the weighted impact of the pandemic
 - COVID-19 infection
 - Post-acute clinically-related COVID-19 harms
 - Post-acute harms due to increased vulnerability following COVID-19
 - Indirect harms due to pandemic related restrictions (restrictions to vital services etc.)
